REC'D 13 APR 2000

WFO PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

# Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet from the Patent Office to help you fill in this form)

1. Your reference

A25770

2. Patent application number

(The Patent Office will fill in this part)

9907442.9

31 MAR 1999

3. Full name, address and postcode of the or of each applicant (underline all surnames)

BRITISH TELECOMMUNICATIONS public limited company  
81 NEWGATE STREET  
LONDON, EC1A 7AJ, England  
Registered in England: 1800000

Patents ADP number (if you know it)

1867002

If the applicant is a corporate body, give the country/state of its incorporation

UNITED KINGDOM

4. Title of the invention

SERVER COMPUTER

5. Name of your agent (if you have one)

GARRISON, Christopher Sinclair

"Address for Service" in the United Kingdom to which all correspondence should be sent (including the postcode)

BT GROUP LEGAL SERVICES  
INTELLECTUAL PROPERTY DEPARTMENT  
HOLBORN CENTRE  
120 HOLBORN  
LONDON, EC1N 2TE

Patents ADP number (if you know it)

1867001

6990493001

6. If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number

Country

Priority application number  
(if you know it)

Date of filing  
(day / month / year)

7. If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application

Number of earlier application

Date of filing  
(day/month/year)

8. Is a statement of inventorship and of right to grant of a patent required in support of this request? (Answer 'Yes' if:

- a) any applicant named in part 3 is not an inventor, or
- b) there is an inventor who is not named as an applicant, or
- c) any named applicant is a corporate body.

YES

(See note (d))

Patents Form 1/77

9. Enter the number of sheets for any of the following items you are filing with this form. Do not count copies of the same document

Continuation sheets of this form

Description	18
Claim(s)	3
Abstract	1
Drawing(s)	7 x 7

Priority Documents

Translations of priority documents

Statement of inventorship and right to grant of a patent (Patents Form 7/77)

Request for preliminary examination and search (Patents Form 9/77)

Request for substantive examination (Patents Form 10/77)

Any other documents (please specify)

11. I/We request the grant of a patent on the basis of this application.  
Signature(s) Date:

*Christopher Garrison* 31 March 1999

**GARRISON Christopher Sinclair Authorised Signatory**

12. Name and daytime telephone number of person to contact in the United Kingdom  
**Mary Chabre** **0171 492 8517**

**Warning**

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

**Notes**

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

## SERVER COMPUTER

The present invention relates to a method of and apparatus for the serving of  
5 computer files. It has application, in particular, to the secure serving of digitally  
signed computer files.

The notion of associating a sign of some form with a document or an object to  
denote, for example, authorship or ownership has long been in existence. It is an  
10 unfortunate reflection on human nature that the related notion of falsely associating a  
sign with a document or with an object to indicate false authorship or ownership has  
also long been in existence.

With the advent of the printing press and the printed document and, more recently,  
15 the digital or electronic computer and the digital or electronic document, the problems  
of the faithful reproduction and the convenient editing or alteration of documents  
have been much ameliorated.

As will be well known, a digital document can typically be altered or copied as many  
20 times as is wished without any change in quality since it is only the digital bits  
representing the information content of the document that are changing. If a digital  
document is created by a first party and then covertly altered by a second party, it  
may well be difficult for a third party subsequently reading the document to tell that it  
has been altered.

25

The advent of networked communication between computers and in particular the  
rise of the Internet and the World Wide Web has meant that vast numbers of  
computers all over the world can now communicate with each other using common  
protocols. Electronic documents are often now made available as Web Pages on a  
30 Web Site.

It will be well known that the World Wide Web (or simply 'Web' hereinafter) has a  
wide variety of associated concepts and standards. A rich source of information

relating to these concepts and standards is the World Wide Web Consortium (<http://www.w3c.org>), a body hosted by the Laboratory for Computer Science at the Massachusetts Institute of Technology (MIT). Concepts such as a 'Web Server', a 'Web Site', a 'Web Page', a 'Web Browser', a 'Hyperlink' and a 'Uniform Resource  
5 Locator' and standards such as 'HyperText Markup Language will be well known.

A problem faced by those parties wishing to distribute content in the form of electronic documents or files, for example, on the World Wide Web, has been the vulnerability of the stored content to deliberate alteration by unauthorised third parties  
10 accessing the content over a communications network.

Should an unauthorised third party manage to access a given Web Server, they might, for example, edit a Web Page stored on that Web Server. When the Web Page is subsequently viewed with a Web Browser, the content of the Web Page would then  
15 reflect the message of the unauthorised third party rather than the original content provider.

It will be appreciated that a wide variety of motives may exist for unauthorised third parties to attempt to subvert the message delivered by a given piece of content but it  
20 is probably safe to assume that in all cases the content provider would prefer not to have the message delivered by its content tampered with and then presented to the browsing world as its own.

A first present day approach to tackling this problem of the vulnerability of stored  
25 content to alteration by unauthorised third parties might attempt to ensure that the stored content is never accessible to unauthorised third parties.

One example of this approach is the use of a so-called 'firewall'. As will be well known a firewall may be used to protect a computer connected to a network by  
30 controlling traffic between the computer and the network such that only certain types of traffic, as defined by the computer administrator, are allowed to pass from the network to the computer or vice versa. In theory this should prevent unauthorised third parties from accessing the computer from the network such that they could alter

the content stored on that computer. Naturally such a firewall cannot protect the stored content from alteration by a malicious user validly operating inside the firewall

In practice it will be well known that real-world implementations of firewalls are often  
5 far from secure.

A second approach, mindful of the fact that the content might have been altered either when stored or during transmission over a communications channel, is to perform a check on downloaded content to see if it has been tampered with.

10

One simple example of this second approach is the use of a so-called 'checksum'. As will be well known a checksum is computed from a given block of data, yielding a value which is then associated with that block of data. If the checksum computation is run again, any change in the data will cause a change in the checksum value.

15 Checksum methods are most often employed as a simple check to detect corruption during transmission of data. In theory then, when a given piece of content is downloaded along with an initial checksum value, a new checksum value can be computed for the downloaded content, which can then be compared with the original checksum value sent along with the content. If the original checksum value and the  
20 newly derived checksum value are the same then there may be some confidence that the content has not been altered after the computation of the original checksum value, which might be either whilst stored or during transmission.

In practice it will be appreciated however, that any unauthorised third party able  
25 enough, for example, to access and tamper with stored content may well be able enough to alter the original checksum accordingly. If this were done then the checksum comparison performed when the content is downloaded would falsely indicate that the content had not been tampered with since its original storage.

30 More sophisticated examples of this second approach involve the use of so-called 'digital signatures'. The theory and practice of digital signatures have become very well known over the past few years as the Internet and more particularly the World Wide Web have experienced exponential growth.

A treatment of digital signatures may, for example, be found in 'Applied Cryptography: Protocols, Algorithms and Source Code in C' by Bruce Schneier, second edition 1996, John Wiley & Sons. A further treatment of digital signatures  
5 may be found in 'PGP: Pretty Good Privacy' by Simson Garfinkel, first edition 1995, O'Reilly & Associates. Terms such as 'public key', 'private key', 'hash function' and 'message digest function' will be well understood.

Digital signature techniques utilise so-called 'public key' cryptographic methods. As  
10 will be well known, public key cryptography uses an algorithmically related pair of keys, a so-called 'public key' and a so-called 'private key', to encrypt messages, rather than the single key of more traditional symmetric key cryptography. The public key is intended to be widely distributed in the public domain whereas the private key must be kept absolutely secret. Crucially, knowledge of the public key does not allow  
15 the private key to be determined. Typically, a message encrypted with a public key is decrypted and can only be decrypted with the corresponding private key. The encryption process is symmetric however such that an encryption operation performed with the private key can be decrypted with the public key. A successful decryption with a given public key guarantees that the message was encrypted with  
20 the matched private key.

Public key cryptography can be used to attempt to secure a communications channel such that content transmitted over that channel cannot be intercepted and compromised. One example of such an application is the Secure Sockets Layer (SSL)  
25 protocol, originally developed by the Netscape Communications Corporation (Mountain View CA, USA). For communication between, for example, a client computer and a server computer, such a protocol first authenticates the server computer using public key cryptography and then shares a symmetric key for use in encrypting all further communication between the client and server computers. A  
30 protocol such as SSL thus both protects against a first server computer pretending to be a second server computer and serving data falsely purporting to be from that second server computer and prevents any unauthorised third party intercepting and altering communications during transmission. Such a protocol is, however, aimed at

the securing of content during transmission, not at solving the problem of the stored content being vulnerable to alteration.

Digital signature techniques using public key cryptography allow checks not only as to 'authentication', guaranteeing that a digitally signed 'document' does in fact originate from the party whose signature the document bears but also as to 'integrity', guaranteeing that the contents of the document have not been tampered with since the originating party digitally signed the document.

10 The process by which digital signatures are employed in order to perform a check on downloaded content to see if it has been tampered with will be discussed below in greater detail having regard to the invention. It will suffice at this point to consider the functionality provided through the use of digital signatures in the following example of the second approach.

15

The Microsoft Corporation (Redmond WA, USA) has developed so-called 'Authenticode™'. Authenticode™ software is installed on client computers and is directed towards checking software that has been downloaded over a network from, for example, a server computer, to see if the software has been tampered with in an unauthorised fashion. Each such piece of code will have been digitally signed. Having regard to a particular piece of digitally signed code downloaded over a network, before the installation or execution of the code, Authenticode™ may check the digital signature to see if it is valid. A selection of a 'high', 'medium' or 'none' Authenticode™ safety setting must be made in the client software. With a 'high' setting Authenticode™ will not allow the installation or execution of code whose associated digital signature proves to be invalid. With, however, a 'medium' setting, Authenticode™ will warn the user that the code is 'untrustworthy' but will allow the option of installing or executing it if the user wishes. With a safety setting of 'none', Authenticode™ provides no such warning.

30

As will be evident, an arrangement such as Authenticode™, checking code downloaded to a client at that client, can only go so far in protecting stored content. Such checking performed at the client will involve the sending of the content in

question to the client computer. In this way, content that has been tampered with will still be sent out over the network to the client. It may be that an arrangement such as Authenticode™ may be configured to deny the installation or execution of an 'untrustworthy' piece of code, but the code still exists at the client and it cannot be  
5 guaranteed that an able enough user could not access it. Alternatively, it is clear that such a configuration can be changed to allow the installation or execution of 'untrustworthy' code if so wished.

It will be appreciated that neither with the first approach to the problem of the  
10 content alteration (attempting to ensure that the stored content is never accessible to unauthorised third parties), nor with the second approach, (attempting to perform a check on downloaded content to see if it has been tampered with), is it guaranteed that the altered content will not be seen.

15 In the first case if, for example, the relevant firewall had been breached and unbeknownst to the Web Site administrator the stored content had been altered, the altered content would be viewed by anyone accessing the Web Page until such time as the Web Site administrator noticed or was informed of the alteration and took corrective action.

20

In similar fashion, in the second case if, for example, the digital signature authentication of the relevant downloaded content had failed, then, as mentioned above, although the content will be deemed 'untrustworthy', it may well be open to the 'downloader' to view or otherwise execute the 'untrustworthy' altered content.  
25 Indeed, a situation can be imagined where the notoriety of a Web Page that had been tampered with by an unauthorised third party is the very reason for persons wanting to view the Web Page, before the Web Site administrator can take corrective action. Again, even if the downloader is prevented from, for example, executing an untrustworthy file, that file has still been sent out over a network and it may well be  
30 possible to access a copy of the file at some point in the process.

In contrast with these present day approaches however, according to the invention there is provided a server computer comprising:

means arranged to store one or more computer files;

means arranged to store one or more digital signatures;

5 each computer file having an associated digital signature;

means arranged to allow a connection between the file server computer and at least one other computer;

10 means arranged to receive requests from another computer for access to at least one computer file stored on said server computer;

means arranged to retrieve the or each requested computer file;

15 means arranged to retrieve the digital signature associated with the or each requested computer file;

means arranged to validate the digital signature associated with the or each requested computer file; and

20

means arranged to provide said other computer with access to the or each requested computer file only when the digital signature associated with the or each respective requested computer file is valid.

25 Advantageously, in this way it is assured that if the computer file storage security is breached and one or more files tampered with, it will not be possible for any external party to see the results of the tampering. No copy of a computer file can leave the file server computer where it is stored, unless the digital signature associated with that computer file has been validated. If the file has been tampered with, then no external  
30 third party will ever be able to obtain a copy of it. There can be no possibility of the message or functionality of the original computer file being subverted by an unauthorised third party to their own ends.

A method of operating a server computer is also provided.

An embodiment of the invention by way of example will now be discussed with reference to the accompanying drawings in which:

5

Figure 1A represents first and second conventional computers connected to a communications network;

Figure 1B represents such a conventional computer;

10

Figure 2 illustrates a procedural flowchart for the digital signing of a digital document;

Figure 3 illustrates the entities involved in the process of Figure 2;

15 Figure 4 illustrates a procedural flowchart for the serving of digitally signed documents;

Figure 5 illustrates a procedural flowchart for the authentication of the digital signature of a digitally signed document; and

20

Figure 6 illustrates the entities involved in the process of Figure 5.

Figure 1A illustrates a conventional general purpose computer 100, suitable for use as a Web Server. Such a computer 100 is illustrated in Figure 1B and will typically have  
25 at least a central processing unit (CPU) 102, read-only memory (ROM) 104, random-access memory (RAM) 106, a storage device such as a hard disk 108, a device for reading from and writing to storage media such as a floppy disk drive 110 for reading from and writing to floppy disks and input and output ports 112 for connection to other devices or communications networks.

30

Returning to Figure 1A, a floppy disk 114 is indicated for the floppy disk drive 110 to read from or write to. The computer 100 is connected to a communications network 116, which in this embodiment is to be understood as the well known Internet. A

second conventional general purpose computer 118, suitable for use as a Web Client, is similarly connected to the Internet communications network 116.

5 The computer 100 may utilise any suitable operating system, well known examples being Microsoft Windows™ NT, Linux or any one of the other many versions of Unix. Application programs may be written in any of many well known suitable languages in which to write application programs, one well known example of which is C++. Such an operating system and application programs may be loaded onto the storage device 108 of the computer 100.

10

The functionality disclosed in accordance with this embodiment of the invention may be implemented as a software module application program to be executed by the computer 100. This software application program may then be stored in any suitable computer readable storage media form, for example on floppy disk 114, for loading  
15 into the computer 100, via the floppy disk drive 110, for execution. A well known alternative would be to store the software application on a CD-ROM (not shown) for loading into the computer 100 via a CD-ROM drive (not shown) for execution. A further well known alternative would be to download the software application program over the network 116, for execution by the computer 100.

20

In this embodiment the computer 100 has one or more software application programs loaded onto it which, when executed, will cause the computer 100 to operate as a Web Server. One or more Web Documents will be stored on the appropriate storage device of the Web Server, as is conventional.

25

One or more software application programs loaded onto the second computer 108, including a Web Browser program, when executed, enable communication using World Wide Web protocols and in particular allow the viewing of Web Pages, for example those hosted on the Web Server computer 100, using a Web Browser.

30

A conventional digital signing process will now be discussed having regard to Figures 2 and 3. It will be appreciated that the structure of Figures 2 and 3 is mirrored; Figure 2 illustrates a procedural flowchart of the process of the digital signing of a digital or

electronic document whilst Figure 3 illustrates in simple fashion the behaviour of the corresponding entities. It will be further appreciated that the steps indicated in the procedural flowchart will be carried out through execution of the software application running on the Web Server 100.

5

By way of example in this embodiment, the Web Documents considered are Web Pages, typically HyperText Markup Language (HTML) documents, stored on the appropriate storage device of the Web Server 100, in this example, the hard disk. It is to be noted however that this example is non-limiting; many other forms of computer  
10 file are equally able to be treated according to the invention (including, for example, documents of formats other than HTML, images in, for example, Joint Photographic Experts Group (JPEG) format and downloadable software programs).

In first step 200 a document is selected for digital signing. Such a document 300 is  
15 illustrated in Figure 3.

In a second step 202, the document to be signed is run through a so-called 'hash' function. The hash function derives a short representation of the document, which is often referred to as the 'hash' of the document. The document to be signed 300 and  
20 the hash of the document to be signed 302 are figuratively illustrated in Figure 3. The hash function and the hash of the document are often alternatively referred to as the 'message digest' function and the 'message digest' respectively. Two well known examples of hash functions are the MD5 and SHA hash functions.

25 It will be well known that the hash of a document produced by a hash function is remarkably sensitive to the contents of the document. If, for example, a text document is altered by so much as the insertion of a full stop, then a hash generated before the insertion of the full stop and a hash generated after the insertion of the full stop will, in general, be completely different.

30

In a third step 204, a digital signature is created by encrypting the hash of the document using a private key. It will be appreciated that this private key might be the private key of any of a number of parties including, for example, the creator of the

content, the owner of the content or the administrator of the content. The notion of an approved signing party with associated approved keys will be discussed below. The hash of the document to be signed 302 and the digital signature 304 are illustrated in Figure 3.

5

Once so created, the digital signature for the document to be signed may be stored on the appropriate storage device of the Web Server 100, in this example, the hard disk.

10 Alternatively in an optional fourth step 206, the digital signature so created is appended to the document to be signed to create a digitally signed document. The digitally signed document 306 is illustrated in Figure 3. The digitally signed document can then be stored on the appropriate storage device of the Web Server 100, in this example, the hard disk.

15

A document serving process according to the invention will be discussed having regard to Figures 1, 4, 5 and 6. Again, it will be appreciated that steps indicated in the procedural flowcharts will be carried out through execution of the software application running on the Web Server 100.

20

Having regard to Figures 1 and 4, in a first step 400, the Web Server 100 receives a request from the second computer 114 for access to a given Web Page stored on the Web Server 100. As will be well known, this request will typically be initiated through the user of the second computer 114 clicking on a hyperlink, the Uniform Resource  
25 Locator (URL) of which points to the given Web Page.

In a second step 402, the Web Page corresponding to the URL request is retrieved from the appropriate storage device of the Web Server 100, in this example, the hard disk.

30

In a third step 404 the digital signature corresponding to that Web Page is also retrieved from the appropriate storage device of the Web Server, in this example, the hard disk. It will be appreciated that if the digital signature had already been

appended to the document in accordance with optional step 206 above, then this step would be performed upon retrieval of the document itself.

In a fourth step 406, the digital signature associated with the document is validated.

5

A procedural flowchart of the process of digital signature validation is illustrated in Figures 5 and 6. This process of digital signature validation provided for in step 406 will now be discussed having regard to Figures 5 and 6 before returning to discussion of the steps as illustrated in Figure 4. It will be appreciated that the structure of  
10 Figures 5 and 6 is mirrored; Figure 5 illustrates a procedural flowchart of the process of digital signature validation whilst Figure 6 illustrates in simple fashion the behaviour of the corresponding entities.

Having regard to Figure 5, in a first step 500, the digital signature associated with the  
15 document is decrypted with a public key, in this case the public key corresponding to the private key first used to sign the hash or message digest of the document. As will be well known this decryption will yield the hash of the document. The digital signature 600 associated with the requested document and the hash 602 obtained through the decryption are illustrated in Figure 6.

20

In a second step 502, the document is again run through the same hash function as was originally used in the process of digitally signing the document. In this way a new hash of the document is derived. The document 604 and the new hash of the document 606 are illustrated in Figure 6.

25

It will be appreciated that if the public key used to decrypt the digital signature associated with the requested document was not the matched public key for the private key used to sign the hash of the document, then the digital signature will not decrypt correctly. As a consequence, the hash of the document obtained through the  
30 decryption will not be the correct one and will not be the same as the new hash of the document. Similarly, it will be further appreciated that if the document has been altered inbetween the signing of the document including the generation of the hash

and the generation of the new hash then the hash and the new hash will not be the same.

Consequently, in a third step 504, the hash of the document and the new hash of the document are compared. The comparison of the hash of the document 602 and the new hash of the document 606 is figuratively illustrated in Figure 6.

If the hash and the new hash are identical then not only is it guaranteed that the party considered to have signed the document did in fact sign the document (i.e. the public key used in the decryption correctly matched the private key used to sign to document) but it is also guaranteed that the document has not been altered since generation of the digital signature (i.e. the hash of the document and the new hash of the document are identical). The comparison of the hash of the document and the new hash of the document returns a result to the authentication question posed in step 406. The digital signature associated with the requested document either passes the validation test or it does not.

Discussion of the document serving process may now return to a consideration of Figure 4.

If the digital signature is validated then, in a fifth step 408, the Web Server proceeds to send the Web Page to the requesting party, in conventional fashion.

It is to be noted that, in a more general case, once the digital signature associated with a computer file has been validated, the server computer could allow access to the computer file other than sending the whole file at once to the client computer. By way of example, the server computer might instead open a communication session with the client computer and stream portions of the file to the client computer as required.

If the digital signature is not validated however, which is to say that either the document has been altered since the digital signature associated with that document was created or that the document was in fact signed by someone other than who

was represented as having signed the document, then the Web Server will not proceed to send the document at all. Instead, in a sixth step 410, the Web Server will send a Web Page to the requesting party informing them that the Web Page that they have requested is not available.

5

In a seventh step 412, the Web Server might, for example, send a message to a system administrator, containing a warning as to the invalid digital signature.

It is to be noted that, at the present time, public key operations are relatively slow, being of the order of 100 to 1000 times more slow than hash functions or symmetric key operations. If a Web Server were to be checking the digital signatures in respect of every document served, it will be appreciated that this might quickly become a performance bottleneck. To ameliorate this problem, it is possible to use dedicated hardware boards optimised for the checking of digital signatures. One example of such a board is the one produced by nCipher of Cambridge, United Kingdom. Each such board will typically allow the checking of several hundred digital signatures per second, with the possibility of daisy-chaining further boards as required.

As mentioned above, it is quite possible that there will be a number of parties who might wish to digitally sign one of 'their' documents. Each such party will have their own private key with which to perform the relevant encryption. It will thus be necessary to provide a means by which each digitally signed file can be associated with the relevant signing party such that the appropriate matched public key can be used for the digital signature authentication.

25

One example of a means by which each digitally signed file may be associated with the signing party is simply to attach a copy of the digital certificate of the signing party to the digitally signed file. Having regard to Figure 2, this might, for example, be performed in a further step following step 206. The well-known concept of the digital certificate, closely related to that of the digital signature, will not be discussed in any detail here. It will suffice to note that a digital certificate binds the identity of a party to the public key of that party and is itself signed by a third party, usually denoted a Trusted Third Party (TTP).

30

In this way, having regard to Figure 4, when a digitally signed file is retrieved in steps 402 and 404, the attached digital certificate would also be retrieved. The digital certificate will provide the identity of the signing party and the associated public key of the signing party. Having regard to Figure 5, this public key may then be used in step 500, to obtain the hash of the digitally signed document as required in the authentication process.

If the digital certificate attached to the file is not the digital certificate of the signing party then the authentication will fail. It is possible to consider however that an unauthorised third party manages to smuggle a digitally signed file onto the Web Server with a matched digital certificate. A subsidiary problem which therefore arises is the controlling of which parties are authorised to sign documents for storing on that particular Web Site.

15

A list of authorised signing parties may be constructed and stored on the Web Server; only the digital certificates of the authorised signing parties may be validly used. Since the next point of attack for an unauthorised third party would be to try and add a false 'authorised' signing party to the list, this list may itself be secured by signing it with the private key of the system administrator. In this way, the list can only be read using the public key of the system administrator which ensures, as with the discussion of the stored documents above, that the list has not been tampered with and does in fact originate from the system administrator.

Another issue which may be of interest is the ensuring that documents with a limited 'life' are not served after a predetermined time or date. Having regard to Figure 2, this might be achieved, in a further step following step 206, through the attachment of an 'expiry time- or date-stamp' to the digitally signed file. To prevent this expiry time-stamp being compromised, the digitally signed document with the attached expiry time-stamp might itself be signed in a yet further step with, for example, the private key of the system administrator.

Having regard to Figure 4, in this instance when the digitally signed document is retrieved, in steps 404 and 404, the digitally signed document would have the expiry time-stamp attached and would be signed by the system administrator. In a further step then, the expiry time-stamp could first be retrieved through the decryption of the  
5 digitally signed document with the public key of the system administrator. In a yet further step, a check could then be performed to see if the relevant time or date had been passed. If the relevant time or date had been passed then the document would not be served.

10 A simple application of this embodiment according to the invention will now be discussed. The Web Server illustrated in Figure 1 is taken to host a corporate Web Site. The Web Server will typically be protected by a corporate firewall as discussed above. Public computers having an Internet connection and being suitably equipped with Web Browsers might then be used to view Web Pages on this corporate Web  
15 Site. As will be well known these Web Pages might typically be used to present information about the company to the world at large.

A first situation might be considered where the company posts a document in the form of a Web Page on its corporate Web Site. The document has been digitally  
20 signed using the private company key in accordance with the above discussion of Figures 2 and 3. A member of the public requests access to this document, typically by clicking on the hyperlink associated with the document. In accordance with the above discussion of Figures 4,5 and 6, the Web Server carries out an authentication of the digital signature of the document. In this first situation the authentication is  
25 successfully carried out and the Web Page served to the member of the public making the request without further ado.

A second situation might now be considered where again the company posts a document in the form of a Web Page on its corporate Web Site. The document has  
30 been digitally signed using, for example a private company key in accordance with the above discussion of Figures 2 and 3. In this situation however, unbeknownst to the corporate Web Site administrator, the corporate firewall has been compromised and an unauthorised third party has gained access to the Web Server. Using this

access, the unauthorised third party has then proceeded to alter one or more of the Web pages stored on the Web Server. The alterations effected by this unauthorised third party will depend on their motives for mounting such an attack; it is however unfortunately easy to conceive of a range of such motives from pranks to outright  
5 sabotage.

A member of the public might now be considered as requesting access to a document which has been altered by the unauthorised third party. In accordance with the above discussion of Figures 4,5 and 6, the Web Server carries out an authentication of the  
10 digital signature of the document. In this second situation the authentication will fail due to the mismatch in the hash of the document and the new hash of the document.

The Web Page will therefore not be served to the member of the public making the request. Crucially, it will therefore not be possible for the member of the public  
15 making the request to see the altered document at all.

As indicated above, if the Web Page altered to suit the motives of an unauthorised third party intruder were allowed to be served to the member of the public making the request, albeit with a warning that the document was 'untrustworthy', then damage  
20 could nonetheless be done to the company's business or reputation.

A third situation might now be considered. In this situation, again unbeknownst to the corporate Web Site administrator, the corporate firewall has been compromised and an unauthorised third party has gained access to the Web Server. Using this access  
25 the unauthorised third party has posted a forged document in the form of a Web Page on the corporate Web Site of the company. The document has been digitally signed by the third party in accordance with the above discussion of Figures 2 and 3 but the private key used in the signing process was one selected by the unauthorised third party rather than that of the company.

30

A member of the public might now be considered as requesting access to a document which has been altered by the unauthorised third party. In accordance with the above discussion of Figures 4,5 and 6, the Web Server carries out an authentication of the

digital signature of the document. In this third situation the authentication will again fail. An attempt to decrypt the digital signature with the company public key when the digital signature was signed with an unauthorised third party private key will again cause a mismatch to occur in the hash of the document and the new hash of the  
5 document.

Yet again the Web Page will therefore not be served to the member of the public making the request and again, crucially, it will therefore not be possible for the member of the public making the request to see the altered document at all.

## CLAIMS

1. A server computer comprising:

5 means arranged to store one or more computer files;

means arranged to store one or more digital signatures;  
each computer file having an associated digital signature;

10 means arranged to allow a connection between the file server computer and  
at least one other computer;

means arranged to receive requests from another computer for access to at  
least one computer file stored on said server computer;

15 means arranged to retrieve the or each requested computer file;

means arranged to retrieve the digital signature associated with the or each  
requested computer file;

20 means arranged to validate the digital signature associated with the or each  
requested computer file; and

means arranged to provide said other computer with access to the or each  
25 requested computer file only when the digital signature associated with the or each  
respective requested computer file is valid.

2. A server computer as claimed in claim 1, in which said means arranged to  
provide said other computer with access to the or each requested computer file only  
30 when the digital signature associated with the or each respective requested computer  
file is valid comprises means arranged to provide to said other computer a copy of the  
or each computer file only when the digital signature associated with the or each  
respective requested computer file is valid.

3. A server computer as claimed in claim 1 or claim 2 further comprising:

means arranged to store a list of approved computer file signing parties;

5 each computer file signing party having at least one associated signing key with which to create digital signatures; and in which

said means arranged to validate the digital signature associated with the or each requested computer file only validates said digital signature if said digital  
10 signature was created with a signing key associated with an approved computer file signing party.

4. A server computer as claimed in any one of claims 1 to 3 further comprising a clock, wherein the or each computer file stored on said server computer  
15 has an associated expiry date; such that:

said means arranged to validate the digital signature associated with the or each requested computer file only validates said digital signature if the expiry date associated with the or each computer file is later than the current clock date.  
20

5. A server computer arranged to store one or more computer files, one or more digital signatures, each computer file having an associated digital signature, said server computer being arranged to perform the operation of:

25 receiving a connection from another computer;

receiving a request from said other computer for access to at least one computer file stored on said server computer;

30 retrieving the or each requested computer file;

retrieving the digital signature associated with the or each requested computer file;

validating the digital signature associated with the or each requested computer file; and

5 providing said other computer with access to the or each requested computer file only if the digital signature associated with the or each requested computer file is valid.

6. A method of operating a server computer comprising:

10

receiving a connection from another computer;

15

receiving a request from said other computer for access to at least one computer file stored on said file server computer; each said computer file having an associated unique digital signature stored on said file server computer;

retrieving the or each requested computer file;

20

retrieving the digital signature associated with the or each requested computer file;

validating the unique digital signature associated with the or each requested computer file; and

25

providing said other computer with access to the or each requested computer file only if the digital signature associated with the or each requested computer file is valid.

30

ABSTRACT  
SERVER COMPUTER

The problem of the vulnerability of electronic content stored on server computers to alteration by unauthorised third parties is one which has become much exacerbated with the advent of the Internet and the World Wide Web. Present day approaches, including approaches based on digital signature techniques, allow for the checking of content transmitted over communications networks to, for example, client computers, to establish if tampering by unauthorised third parties has occurred. Such approaches all suffer from the disadvantage that any content which has been tampered with is still transmitted over the network to the client computer before such a check takes place. According to the invention however, a server computer storing computer files, each computer file having an associated unique digital signature, receiving requests for access to one or more such computer files, only allows access to the or each computer file if their associated digital signatures are valid. Thus, if a computer file has been tampered with by an unauthorised third party, the digital signature associated with that computer file will prove to be invalid when checked and the server computer will not serve the computer file at all. In this way, a computer file that has been tampered with can never leave the server computer, much improving the security of the stored computer files.
